I. Project Objectives

Goal: Evaluate component level design constraints to assist in system level electrostatic discharge (ESD) requirements for Touch and Display Driver Integration (TDDI) ICs. Optimize ESD protection scheme to provide better protection against system level tests.

II. Motivation

- Standard component level ESD testing is insufficient to predict the outcome of system level ESD performance in the case of TDDI ICs.
- A TDDI IC that meets JEDEC specifications will not necessarily meet system level IEC specifications due to the unique constraints of an assembled TDDI liquid crystal display.

III. ESD Overview

ESD Testing

Component Level Testing
- Simulated discharge through skin of an inadequately grounded person
- Intended to protect a component during manufacturing processes
- Typical Component level testing is done to JEDEC Human Body Model (HBM) and Charged Device Model (CDM)

System Level Testing
- Simulated discharge of an ungrounded person through a metal object (such as a tool or a connector)
- Intended to protect the end item from normal usage ESD stress
- System level testing is done to IEC 61000-4-2 standards

IV. Experimental Results

I-V Response of Primary ESD Devices under Transmission Line Pulse (TLP) Stimulus

- Gate Coupled NMOS Clamp Performance
- Perimeter Diode vs Area Diode

V. Conclusions

Initial experiments show that system level ESD stress is better modeled using a TLP stimulus. Future work will be needed to evaluate the ability of TLP stimulus to predict the IC performance in system level ESD testing.

Additional test chips could develop multi-staged ESD protection to incorporate silicon controlled rectifiers, potentially reducing the cost impact of ESD protection.
